

Phase-2: Requirement Analysis & Scope Specification

Project: Auto Ticket Classification using Flow Designer | Target: u_incident_workflow | Scope: Global

2.1 Functional Requirements Matrix

The solution must satisfy rigorous functional benchmarks to meet operational and institutional audit standards:

Req ID	Requirement Name	Technical Specification & Success Criteria
FR-01	Automated Issue Parsing	System must inspect the 'Short Description' field upon record creation and automatically assign Category and Subcategory.
FR-02	Taxonomy Dependency	Subcategory choices must dynamically filter based on the chosen Category to preserve relational database integrity.
FR-03	Sequential Auto-Numbering	Every incident must automatically receive a padded, sequentially incremented identifier (e.g., INC0001001).
FR-04	Caller Feedback Notification	An outbound SMTP confirmation email must be generated and queued to the caller's email upon creation.
FR-05	Lifecycle & State Tracking	Ticket state must initialize to 'New' with support for In Progress, On Hold, Resolved, and Closed states.

2.2 Non-Functional & Security Requirements

- **No-Code Maintainability:** The workflow must remain 100% no-code within ServiceNow Flow Designer so system administrators can modify keywords without script editing.
- **Access Governance (RBAC):** Table-level CRUD access must be restricted to designated roles (u_incident_workflow_user) and system administrators via Access Control Lists (ACLs).
- **Portability & Packaging:** All database dictionaries, choice lists, ACLs, forms, and flows must be packaged inside a single Global Update Set for clean promotion.

Scope Confirmation: Scope is bounded strictly to ticket intake, automated categorization, dependent choice population, and notification dispatch on table u_incident_workflow.
